

Recap of JS

"Everything in Javascript happens inside an 'Execution Context'"

(*) Javascript is a Synchronous Single-Threaded language
(Synchronous Single Threaded)

↳ Code will execute one by one

2) In the First Phase of memory Allocation, the Execution Context store the variable and function, with the special value which is undefined for variable.
(*) For ~~the~~ Function It will store whole body inside memory creation.

Var n = 2

function Square (num),

Var ans = num * n

return ans;

}

Var Square 2 = Square (n)

Var Square 4 = Square

(*) In Phase two, code executes line by line. Assigning the variable to the liven value. Goes to function which is already in Execution Context.

(*) Next it will go to function invocation which creates separate "Execution Context" inside the main Execution Context". (Square(n))
Phase I

Memory	Code						
n = 2 Square: { ... }	<table> <tr> <th>memory</th><th>Code</th></tr> <tr> <td>num: undefined</td><td></td></tr> <tr> <td>ans: undefined</td><td></td></tr> </table>	memory	Code	num: undefined		ans: undefined	
memory	Code						
num: undefined							
ans: undefined							
Square 2: undefined							
Square 4: undefined							

Phase - II

Memory	Code						
n : 2 Square: { ... }	<table> <tr> <th>Memory</th><th>Code</th></tr> <tr> <td>num: 2</td><td></td></tr> <tr> <td>ans: 4</td><td>return</td></tr> </table>	Memory	Code	num: 2		ans: 4	return
Memory	Code						
num: 2							
ans: 4	return						
Square 2: 4							
Square 4: undefined							

The "Execution Context"

(*) Another Function Invocation is called i.e (Square 4)
It creates another "Execution Context" with Phase I order that stores data and executes the code next.

Phase I

Memory	Code				
n: 2 sq: { ... }	<table> <tr> <th>Memory</th><th>Code</th></tr> <tr> <td>num: undefined ans: undefined</td><td></td></tr> </table>	Memory	Code	num: undefined ans: undefined	
Memory	Code				
num: undefined ans: undefined					

Memory	Code
num: undefined ans: undefined	

Phase II

Memory	CODE				
n: 2 sq: { ... }	<table> <tr> <th>Memory</th><th>Code</th></tr> <tr> <td>num: 4 ans: 16</td><td>Return ans.</td></tr> </table>	Memory	Code	num: 4 ans: 16	Return ans.
Memory	Code				
num: 4 ans: 16	Return ans.				

(*) When return statement is reached, will go back to the variable that stored function.

(*) After that this "Execution context" be deleted.

(*) When the Program finished, Context also get deleted.

Call Stack

(*) JS has its own Call Stack which used to store the Execution Context Inside.

Phase I

When function is invoked
Global Execution Context.

Phase II

(*) Once the function over, E1 moved out and gives control to Global Execution Context.

(ii) When another function Involved It will create new Execution Context and moved to Call Stack as E2

(iii) When function gets over E2 will move out and give control to GEC

(*) This is how Javascript manage the execution context creation, deletion and everything is controlled by js.

(*) After the execution of whole program, the call stack will be empty as there is "no execution context".

Call Stack has many names :-

(i) Execution Context Stack

(ii) Program Stack.

(iii) Control Stack.

(iv) Runtime Stack.

(v) Machine Stack.

③ Hoisting

(*) The variable and function are stored in memory creation before execution of the code.

undefined

~~When we initialize value after the call function~~

~~It shows undefined~~

(*) When execution creation created it stores value for variable and functions.

Not-defined

(*) When we fail to initialize the value for the particular variable.

Any where in the program it shows not-defined.

```

    getname();
    var getname2 = function() {
    }
    var getname3() {
    ...
    }

```

→ undefined
 Both function
 Because the getname
 are considered as variables

(*) Call Stack execution in editor (not in browser)

① var a;

console.log(a);

if (a === undefined) {

console.log("a is undefined");

}

else {

console.log("a is not undefined");

}

Output → undefined
 a is undefined

(*) JavaScript is a loosely typed language i.e. it doesn't attach any variables to the specific datatype

(*) also known as weezy typed language (Heater)

Undefined → It's like a placeholder which kept inside the variable and in the whole block of code, that variable doesn't assign any variable.

Scope :- (depends on local environment)

(*) It means where you can access a specific variable (or) function in the code.

eg:-

c() →

a() →

Global
Execution
Context.

M	C
M	C
b: 10 c: {...}	
M	C
a: {...}	

function a() {

var b = 10;

c();

function c() {

}

}

a();

console.log(b);

Lexical Environment

(*) ~~Lexical Environment~~

(*) Whenever the Execution Context is created, a Lexical Environment also created.

(*) Lexical Environment is the local memory along with the lexical environment of its parent.

Lexical \Rightarrow Hierarchy, Sequence of.

Eg:-
Function a() {
 var b = 10;
}

\rightarrow a() lexically inside the Global Execution Context.

c();

Function c() {
}

\rightarrow In c is lexically inside the fn. a().

(*) In that Order, the Lexical Environment of GEC is Null, because there is nothing outside GEC.

Scope chain :-

(*) Nothing But the chain of lexical environment and parent references.

let and Const

(*) let and Const declarations are Hoisted

let a = 10;

console.log(a);

var b = 100;

(*) Before execution the memory of a is stored in separate memory location and b is stored in Global EC because of (let & var) difference.

Temporal dead zone :- (TDZ)

Refers to the time between when a variable is declared using let or const and when it is initialized.

let a ;
a = 10 ; } → Time Between these two is called Temporal Dead Zone.

Window.b => Show output

Window.a => undefined => But let & const.

(*) Because "a" is not present in window object
is "Global Execution Context".

(*) Var can allow multiple declaration with the same reference.

Eg:: var b = 10;
var b = 100;

=> This works fine But when we use "let" instead

Eg:: let a = 10;
let a = 100;

=> Shows Syntax Error Cause let won't allow same reference in the scope.

=> Const => Stores in separate memory location like "let"

But "const" shows initialize immediate of declaration

Const a = 100; \Rightarrow But if we do like 'let'

i:-

Const a ;	{ Shows syntax error which shows missing initialised.
a = 100 ;	

(Type error)

Const b = 100 ;	{ Shows error as assignment to constant variable.
b = 100 ;	

Type error

- \Rightarrow In above code, Const variable trying to assign new value to b which result in Type error. Because
- \Rightarrow We cannot modify or reassign value to "Const" variable that is why type error. (Type of b = Const) \Rightarrow ~~Changing~~ trying to change the Type error.

Reference error

Eg:- console.log(a) Shows 'Reference error' cannot
let a = 100; access 'a' before initialization.

In Short

- Const \Rightarrow use when you do reassign another value
- let \Rightarrow let is best option as it is used separate memory and has better feature than Const.
- Var \Rightarrow Old, we very consciously cause create problems in

③ Closures

(*) Closures is the combination of a function bundled together to the lexical environment.

Other words

(*) Function along with the lexical environment is called Closures.

(or)

(*) A Closures gives access to the outer function scope from the inner function scope.

Eg: function x() {

var a = 7;

function y() {

console.log(a);

}

return y; Closure.

}

var z = x();

console.log(z);

z();

Uses of Closure

(*) Modul

(*) Curre

(*) Fun

(*) m

(*) m

(*)

(*)

(*)

③.

Funct

(*)

Fun

(*) Module Design Pattern

(*) Cursing

(*) Functions life Once

(*) Memoize

(*) Maintaining State in async world.

(*) SetTimeouts.

(*) Iterators

(*) and many more....

⑦.

Function Statement :: (or) Function Declaration

(*) The way of declaring the function is called

Function Statement.

(or)

(*) When you define a function using function like
And it gets hoisted.

eg:-

```
fn. greet() {
```

```
  console.log("Hello");
```

```
}
```

```
greet();
```

works when you
call it before the
declaration

↳ When a function is assigned to a variable. While function statements, function expressions are not hoisted.

Eg:-
`greet();`
`const greet = fn() {`
 `console.log("Hello");`
`}`

It won't work because of its not hoisted

Anonymous Function

Functions
(*) ~~Name~~ without name is called Anonymous fn.

Eg
`Function() {`
`}` } Anonymous function.

(*) Anonymous functions are used when the functions are used as values.

Eg:-
`var b = fn() {`

`}`

`b();`

→ Here Calling the function without the name.

(*) If we give name to the function in an function expression is called named function expressions.

eg

```
Var b = function xyz() {  
  console.log("b called");  
}
```

a();

b();

xyz(); → Shows error because fn. xyz is stored as variable b

Parameter:-

(Pass)

(*) When ^{we} use value (or) variable in the function bracket of the function is called parameter

eg

function school (name, age) {

var stu1 = name, age;

~~stu1~~ =

Arguments :-

(*) It is the actual value that you pass to the

function when you call it. eg:- school(jarvis,

Q1

First Class Functions :- (or) First class Citizens

(*) The ability to use functions as values.

Eg:- passing functions in function,
return function inside function,
Assigning to the variables.

Arrow functions :- [ES 06]
